

Heat-stable/controlled temperature chain (CTC) qualified dry formulations

Comparators* : Use without innovation (i.e. current liquid or lyophilized formulation)

Section 1: Summary of innovation

1.1 Examples of innovation types:

Lyophilised formulation

Image source: ^a

Foam-dried, freeze-dried, and spray-dried formulations

Image source: ^a

1.2. Description of innovation:

The controlled temperature chain (CTC) is an innovative approach to vaccine management allowing vaccines to be kept at temperatures outside of the traditional cold chain of +2°C to +8°C for a limited period of time under monitored and controlled conditions, as appropriate to the stability of the antigen. A CTC typically involves a single excursion of the vaccine into ambient temperatures not exceeding +40°C and for a defined duration, just prior to administration.^b An example of a CTC qualified vaccine is the meningococcal A conjugate vaccine, MenAfriVac, which was granted a label variation by the appropriate National Regulatory Authority and WHO for its use in a CTC at temperatures of up to 40°C for four days.^c

The innovation being assessed refers to dry formulations that are heat-stable and CTC-qualified. Vaccines with these attributes are able to be exposed to ambient temperatures below a defined threshold temperature without losing their potency and have received regulatory and WHO prequalification approvals to allow CTC storage. Dry formulations vary in their sensitivity to heat and suitability for use in a CTC. Therefore, this innovation only considers a subset of dry formulations that meet these criteria.

Currently all dry vaccine formulations that are commercially available require reconstitution with a diluent and are delivered in a liquid presentation (injectable and oral routes). New delivery technologies, such as

* Single dose vials, rather than multi-dose vials (MDVs) were used for the comparator, because in most cases the innovation being considered is a single-dose presentation. However, when multi-dose vials are commonly used by countries for specific vaccines, a comparison against the multi-dose vial will also be conducted under Phase II for those vaccines if this innovation is prioritised.

microarray patches and intra-nasal powder delivery devices) that incorporate novel dry formulations of vaccines are assessed in other technical notes (TN).

Drying vaccines to improve heat stability

Vaccines, in particular live-attenuated vaccines, are unstable when exposed to excessive heat. This results in protein degradation, dissociation of molecules and reduced potency. All of these degradation pathways are exacerbated by the presence of water. Therefore, these vaccines are more stable as a dry product with a low-moisture content of typically less than 3%(1). As a dry product, they are also not freeze-sensitive (2).

Each vaccine antigen has different inherent stability properties, and each dried vaccine formulation will have different stability at specific high-temperatures and will differ in whether it is eligible for CTC and if so, the length of time it can stay in CTC at a particular temperature-threshold. For instance, measles vaccines have moderate heat-stability (VVM14) whereas rabies vaccines (inactivated, but lyophilised) are very heat-stable (VVM30).^d

Vaccine formulations are highly complex, and customized mixtures of excipients as well as drying methods are required to ensure formulations are stable in terms of pH, ionic strength, osmolality and other chemical/physical interactions, and to maintain vaccine potency(3).

Common drying processes are described below:

Freeze-dried formulations:

- Lyophilization is a complex multi-stage, batch process involving three stages: (I) freezing, (ii) primary drying and (iii) secondary drying to transform a liquid into a dry solid product, resulting in a dried cake in the final container which requires reconstitution before administration (refer to image).
- This method is used on an industrial scale, in particular for live-attenuated vaccines, and can also be used to produce dissolvable tablets for oral delivery (see separate technical note)(4)
- Several compounds/excipients (e.g. sucrose, amino acids, gelatine or serum albumin) are incorporated into the freeze-dried formulation in order to protect the formulation against chemical and physical degradation during the freeze drying process(5).
- Lyophilized formulations are freeze-resistant and typically stored within the cold chain(2).

Foam-dried formulations:

- Foam drying is a desiccation process, whereby a solution is transformed into a dried foam structure in one single step. The method involves boiling or foaming of the solution under reduced vapour pressure followed by rapid evaporation, leaving behind a solidified foam structure(6).
- Unlike lyophilisation, there is no freezing step, so it can be used with freeze-sensitive vaccines.

Dry-powder formulations:

- Various processes can produce dry powder formulations – they include spray-drying, spray-freeze drying, and supercritical fluid drying. All of these methods result in the formation of a ‘free-flowing’ dry-powder with a defined particle size, that does not necessarily need reconstitution before administration (2). While research has been conducted applying these methods to vaccines, there are no commercially available vaccines produced by these methods.
- One-step processes include:

^d https://www.who.int/immunization/programmes_systems/supply_chain/resources/VaccineStability_EN.pdf

Category: Formulations

Innovation: Heat stable, CTC qualified dry formulations

Comparators: Current liquid/lyophilized formulation

- **Spray drying** is a continuous drying process based on direct contact with hot air at atmospheric pressure that results in the production of a dispersed fine powder(7). It is an established technique commonly used in the food, pharmaceutical and chemical industry.
- **Spray-freeze drying** Involves atomisation, freezing and drying, thus it combines elements of both spray drying and freeze drying. It can be carried out as a continuous process(8).
- **Supercritical fluid drying** is a mild single-step process that can transform fluids into a fine dry powder keeping proteins stabilized.
- Two-step processes include:
 - A combination of first drying the product (i.e. freeze-drying, vacuum drying, foam-drying) and then reducing the particle size to produce a powder form (i.e. milling). However, the additional production step can lead to contamination, damage the vaccine, and increase production costs (9).

CTC qualification

Several licensed vaccines are sufficiently stable for CTC qualification in their current formulation. For these vaccines, manufacturers need to conduct stability testing to support a CTC label indication and obtain a label variation allowing CTC use from the appropriate National Regulatory Authority and WHO. Vaccines in development can be optimized for heat stability as either dry or liquid products (see the Heat-Stable CTC Qualified Liquid Formulations Technical Note) and receive a CTC label indication during their initial licensure - often with minimal investment for this added feature.

For this analysis, we are assuming that the innovation results in a dried, heat-stable vaccine in a single-dose vial that is qualified for use in a CTC, requires reconstitution, and is delivered by injection.

Innovation: *Heat stable, CTC qualified dry formulations*

Comparators: *Current liquid/lyophilized formulation*

SECTION 2: Summary of assessment for prioritisation

2.1 Key benefits:

- Heat-stability/CTC-qualification can increase access to difficult to reach populations.
- Heat-stability/CTC-qualification can enable alternative delivery scenarios and simplify supply chain logistics.
- The innovation can alleviate constraints on cold chain logistics and storage (in areas where cold chain storage is limited or not available).
- Improving the heat stability of vaccines can also protect against damage caused by inadvertent heat-exposure.

2.2 Key challenges:

- Dry formulations require reconstitution, which increases the number of components, storage space required, complexity of vaccine preparation, number of sharps, and risk of contamination.
- In multidose presentations, dry formulations without preservative increase vaccine wastage and missed opportunities compared to liquid vaccines as the reconstituted vaccine must be discarded at the end of the vaccination session, making health care workers reluctant to open a vial.

2.3 Additional important information

- CTC qualification can be obtained for vaccines during initial licensure or through a label variation process if stability testing results are available to justify the higher temperature storage recommendations.
- Developing a heat-stable/CTC-qualified dry formulation can be technically challenging for some vaccines and there are constraints depending on the vaccine type and the antigen of interest. There is no single formulation method that will stabilize all vaccines; each vaccine requires a customized approach.
- Freeze-dried formulations are the only dry formulations that are commercially available. Other drying methods (e.g. spray-drying, spray-freeze drying) have been used in the food and pharmaceutical industries, but there are no licensed vaccines produced using these technologies.

Innovation: Heat stable, CTC qualified dry formulations

Comparators: Current liquid/lyophilized formulation

SECTION 3: Evaluation criteria

3.1 Health impact criteria

Indicator: Ability of the vaccine presentation to withstand heat exposure

Legend: **Green**: **Better** than the comparator: The innovation includes features that may increase heat stability; **White**: **Neutral**, no difference with the comparator; **Red**: **Worse** than the comparator: The innovation includes features that may decrease heat stability, **N/A**: the indicator measured is **not applicable** for the innovation; **Grey**: **no data** available to measure the indicator.

Table 2.

| Ability of the vaccine presentation to withstand heat exposure | Parameters to measure against a comparator | Liquid comparator | Lyophilised comparator | Assessment |
|--|--|-------------------|------------------------|--|
| | Does the innovation have features that may improve heat stability? | Better | Better | Compared to current vaccines, heat stable dry formulations that are CTC-qualified are more heat stable. The minimum requirement for CTC qualification is stability at 40°C for at least 3 days, immediately prior to administration. (2) |
| | | Liquid | Lyophilised | Better than both the liquid and lyophilised comparators |

Indicator: Ability of the vaccine presentation to withstand freeze exposure

Legend: **Green**: **Better** than the comparator: The innovation includes features that may increase freeze resistance; **White**: **Neutral**, no difference with the comparator; **Red**: **Worse** than the comparator: The innovation includes features that may decrease freeze resistance, **N/A**: the indicator measured is **not applicable** for the innovation; **Grey**: **no data** available to measure the indicator.

Table 3.

| Ability of the vaccine presentation to withstand freeze exposure | Parameters to measure against a comparator | Liquid comparator | Lyophilised comparator | Assessment |
|--|---|-------------------|------------------------|--|
| | Does the innovation have features that may improve freeze resistance? | Better | Neutral | Lyophilized vaccines are not freeze-sensitive and therefore there is no difference in freeze sensitivity compared to a heat-stable dry presentation. It is possible that vaccines that are freeze-sensitive in liquid formulation might be less sensitive to freeze-damage when in a dry formulation due to the lower moisture content. |

Category: Formulations

Innovation: Heat stable, CTC qualified dry formulations

Comparators: Current liquid/lyophilized formulation

| | | |
|--------|-------------|--|
| Liquid | Lyophilised | Better than the liquid comparator No difference to the lyophilized comparator |
|--------|-------------|--|

3.2 Coverage and equity criteria

Indicator: Ease of use¹

Legend: **Dark Green:** **Considerably better** than the comparator: *Better for all* applicable parameters; **Green:** **Better** than the comparator: *Better for some of the applicable parameters AND no difference* for the rest of the parameters; **White:** **Neutral**, no difference with the comparator; **Yellow:** **Mixed:** *Better than the comparator for some of the applicable parameters AND worse than the comparator for the rest of the parameters;* **Red:** **Worse** than the comparator: *Worse for some of the applicable parameters AND no difference for the rest of the parameters;* **Dark Red:** **Considerably worse** than the comparator: *Worse for all applicable parameters;* **N/A:** the indicator measured is **not applicable** for the innovation; **Grey:** **no data** available to measure the indicator.

Table 4.

| Ease of use | Parameters to measure against a comparator | Liquid comparator | Lyophilised comparator | Assessment |
|---|--|-------------------|------------------------|---|
| <ul style="list-style-type: none"> Assessment of the potential for incorrect preparation based on usability data from field studies (or based on design of innovation if field studies not available) Assessment of the potential for incorrect administration based on usability data from field studies (or based on design of innovation if field studies not available) | Does the innovation avoid reconstitution and is that an improvement? | Worse | Neutral | A dry presentation is scored neutral compared to a current lyophilized presentation since they both require reconstitution. A current liquid presentation does not require reconstitution. |
| | Does the innovation require fewer vaccine product components? | Worse | Neutral | A dry presentation has the same number of components compared to a current lyophilized presentation (2) and more components compared to a current liquid presentation (1). |

¹ Ease of use can prevent missed opportunities resulting from the complexity of preparation and administration procedures. It could also impact the ability for lesser trained personnel to administer the vaccine (incl. self-administration). It can be assessed based on usability data from field studies (or based on design of innovation if field studies not available).

Comparators: Current liquid/lyophilized formulation

Indicator: Total economic cost of the time spent by staff per dose

Legend: **Dark Green**: **Considerably better** than the comparator: *Reduces time for all applicable parameters*; **Green**: **Better** than the comparator: *Reduces time for either, and there is no difference for the other one*; **White**: **Neutral**, no difference with the comparator; **Yellow**: **Mixed**: *Reduces the time for one of the parameters, and increases the time for the other parameter*; **Red**: **Worse** than the comparator: *Increases the time for either of the applicable parameters; and there is no difference for the other one*; **Dark Red**: **Considerably worse** than the comparator: *Increases time for all applicable parameters*; **N/A**: the indicator measured is **not applicable** for the innovation; **Grey**: **no data** available to measure the indicator.

Table 10.

| Total economic cost of the time spent by staff per dose | Parameters to measure against a comparator | Liquid comparator | Lyophilised comparator | Assessment |
|---|---|-------------------|------------------------|--|
| | Does the innovation have attributes that can save time for the vaccinator in preparing and administering the vaccine? | Worse | Neutral | A CTC-qualified dry formulation requires more preparation steps/complexity compared to a current liquid presentation. A CTC-qualified dry formulation requires the same preparation steps and level of complexity as a current lyophilized presentation. |
| | ^o Does the innovation have attributes that save time for staff involved in stock management? | Neutral | Neutral | Similar to the comparator, the innovation does not have attributes that save time for staff involved in stock management. |

| | | |
|--------|-------------|---|
| Liquid | Lyophilised | Worse compared to the liquid comparator Neutral compared to the lyophilized comparator |
|--------|-------------|---|

Indicator: Total economic cost of one-time/upfront purchases or investments required to introduce the vaccine presentation and of recurrent costs associated with the vaccine presentation (not otherwise accounted for)

Legend: **White**: **Neutral**: *NO* there are no one-time/upfront or recurrent costs and this is not different than the comparator; **Red**: **Worse** than the comparator: *YES* there are one-time/upfront or recurrent costs.

^o This parameter only applies to barcodes and RFID to capture the benefits for stock management processes, not based on the number of components, but the specific features of the innovation.

Category: Formulations

Innovation: Heat stable, CTC qualified dry formulations

Comparators: Current liquid/lyophilized formulation

Table 11.

| Total economic cost of one-time/upfront purchases or investments required to introduce the vaccine presentation and of recurrent costs associated with the vaccine presentation (not otherwise accounted for) | Parameters to measure against a comparator | Liquid comparator | Lyophilised comparator | Assessment |
|---|--|-------------------|------------------------|--|
| | Are there one-time upfront costs that will be incurred for use of this innovation or recurrent costs that will be incurred for use of this innovation? | Neutral | Neutral | No. Similar to the comparator, there are no upfront or recurrent costs required with this innovation (other than training costs which would be required with any innovation). |

| | | |
|---------------|--------------------|---|
| <i>Liquid</i> | <i>Lyophilised</i> | No difference to both the comparators. |
|---------------|--------------------|---|

3.5 Secondary criteria on potential breadth of innovation use

Indicator: Applicability of innovation to one or several types of vaccines

Table 12.

| Applicability of innovation to one or several types of vaccines | Assessment |
|--|--|
| <ul style="list-style-type: none"> To what types of vaccines/antigens does the innovation apply to, based on technical feasibility? | <p>This innovation could be applied to any vaccine that is currently or can potentially be reformulated into a thermostable dry presentation. Some drying process might not be compatible with aluminum-salt-based adjuvants. Vaccines that are currently liquid and adequately heat-stable would not be appropriate for this innovation since their current liquid format has benefits in terms of ease-of-use and lower costs (i.e. HPV vaccine). The benefits of CTC-qualification are greatest for vaccines that are used in campaigns or special strategies (i.e. meningococcal group A conjugate vaccine).</p> <p>Ebola and MR are other VIPS antigens that could be suitable for this innovation.</p> |

Category: Formulations

Innovation: Heat stable, CTC qualified dry formulations

Comparators: Current liquid/lyophilized formulation

Indicator: Ability of the technology to facilitate vaccine combination

Table 13.

| <p>Ability of the technology to facilitate novel vaccine combinations</p> <ul style="list-style-type: none"> Does the innovation facilitate novel combination vaccine products? | <p>Assessment</p> |
|---|---|
| | <p>Developing heat-stable dry formulations by lyophilisation will not facilitate novel combinations, and might not be suitable for existing combinations, either because of a requirement for adjuvant, or because the stabilising excipients needed for the individual components are not compatible.</p> <p>Drying processes such as spray-drying that produce free-flowing powders should permit novel combinations of vaccines, because it should be possible to mix incompatible components as powders after drying and maintain stability.</p> <p>CTC qualification might be more difficult with combination vaccines, as the individual components will have different stability profiles, and the storage requirements will be limited by the least-stable component.</p> |

SECTION 4

4.1 Robustness of data:

Table 14.

| <p>Category</p> | <p>Assessment</p> |
|---|--|
| <p>Type of study</p> | <p>The assessment is based mainly on expert opinion. Some data from peer-reviewed publications on drying-processes has been used to assess applicability and status of the technologies.</p> |
| <p>Inconsistency of results</p> | <p>N/A</p> |
| <p>Indirectness of comparison</p> <ul style="list-style-type: none"> Indicate the setting in which the study was conducted (low, middle or high income setting); Comment if the data is on non-vaccine application of the innovation | <p>All the data assessed has been for vaccine applications</p> |

| | | |
|-----------------------------------|------------------------|---|
| <p>Overall assessment:</p> | <p>Low to Moderate</p> | <p>The quality of data available scores moderate based on the large-scale implementation data available for</p> |
|-----------------------------------|------------------------|---|
